## Dyrobex Learning Module

If we take a look at the basic characteristics of rotor bearings, we can see that the bearing stiffness between the rotor and the bearing pad is critical and that the pad stiffness is less critical. The number of bearings and the chosen bearing stiffness, with respect to the loads that are to be expected, determines the stiffness of the bearing system. The bearing pad softens the system in a certain way and takes up some of the forces transferred from the rotor (see page 113). A bearing pad is a device that transfers load from a rotor to a foundation. The principal function of a bearing pad is to provide a soft path to accept the forces that the rotor applies to the foundation, which were transferred from the rotor via the bearing. Since the bearing pad is a soft device, its stiffness must be less than the rotor. In contrast, the rotor is a hard device and its stiffness should be greater than the bearing pad. The stiffness of the bearing system is governed by the product of the bearing pad stiffness and the rotor stiffness. This is illustrated in the drawings: the rotor positions 0 and 1 are the stiffest position relative to the bearing pad, positions 2 and 3 have intermediate stiffness, and position 4 is the weakest. Position 5 is the only position where the rotor is fixed. The rotor stiffness is therefore 100. The corresponding stiffness of the bearing pad is 0, since the bearing pad stiffness equals the rotor stiffness. From this, the stiffness of the bearing system is 100, since it is the product of the rotor stiffness and the pad stiffness. A rotor/pad system can be characterized as having different degrees of stiffness. The stiffer the rotor, the softer the pad should be. Conversely, the softer the pad, the stiffer the rotor should be. We can differentiate between three basic degrees of stiffness (see table 1): Very low stiffness: The rotor is very soft relative to the bearing pad. From this it follows that the bearing pad, which is relatively hard, acts like a stress carrier for the rotor, which is soft. This type of bearing has a large surface of contact and is described as a ball bearing with a large contact surface. Such bearings have relatively low bearing stiffness. They are usually loaded with small loads and are used in bearings where a large surface of contact is desired. Table 1: Different bearing stiffnesses

A low stiffness rotor/pad system is characterized by a large surface of contact and a large tangential contact force. It is therefore called a

The profile for each pad area can be changed by changing the dropdown list, and you can also add or remove the pad area. You can add a new pad area or move an existing one by simply clicking the pad to the left or to the right of the area. Measuring Pad Change the field by which the PAD is measured. - Index: Repeating Views of the PAD - Single View of the PAD. .02. The problem in the example is that the first ring represents the time required to obtain the friction loss values for each. Free pad thrust bearing design programs: as it happens without considering cost and in software that does not support other aspects. .e. Free Tool: C-AD (computed additive design): Dyrobes.
